1. Adversarial Agent Debate Market

Two AI agents take opposing positions on a token (bull vs bear). They argue onchain — each agent's "conviction score" is backed by real liquidity staked via Uniswap. As one agent wins the debate round (judged by a third neutral agent over AXL), funds automatically flow to the winning side. It's prediction markets meets AI debate. Nobody has built this.

Tracks: Uniswap (swap/liquidity) + Gensyn AXL (agent debate communication) + KeeperHub (reliable execution of conviction-based swaps)

🧠 Adversarial Agent Debate Market — Full Breakdown

Core Concept in One Line

Bull and Bear AI agents publicly debate a token's future price, back their arguments with real staked liquidity, and the winning side's conviction automatically gets executed as a Uniswap swap — all coordinated peer-to-peer over AXL with KeeperHub guaranteeing execution.

🏗️ System Architecture

User deposits funds → Chooses Bull or Bear side

👥 The Three Agents in Detail

● Bull Agent

Takes a long position on a chosen token (e.g., ETH/USDC pair)

Every round, it constructs an argument using:

Onchain data (price momentum, volume, whale wallet activity)

Optionally: web search for recent news

Publishes its argument as a structured message over AXL

Its "conviction score" starts at 50 and moves up/down based on judge verdicts

When conviction crosses a threshold → triggers a buy swap on Uniswap

Bear Agent

Takes the short/sell position on the same token

Same structure as Bull Agent but argues the opposite

Pulls bearish signals — negative sentiment, liquidity outflows, macro data

When conviction crosses threshold → triggers a sell/swap to stablecoin on Uniswap

Judge Agent

Completely neutral, runs on a separate AXL node

Receives both agents' arguments each round

Scores them on:

Quality of evidence cited

Logical consistency

Predictive accuracy of previous round (did the price move as argued?)

Publishes verdict over AXL — this is what triggers fund movement

Cannot be influenced by either Bull or Bear (separate node, no shared memory)

One Full Debate Round (Step by Step)

Round Start

- Bull Agent constructs argument
 - "ETH whale accumulation up 23%, EIP upgrade incoming, volume/price divergence suggests breakout"
 - Publishes to AXL → all nodes receive
- Bear Agent constructs counter-argument
 - "Macro risk-off environment, ETH staking outflows, RSI overbought at 78, similar setup to March 2024 dump"
 - Publishes to AXL → all nodes receive
- Judge Agent reads both arguments
 - Scores Bull: 62/100
 - Scores Bear: 71/100
 - Bear wins this round
 - Publishes verdict to AXL

💰 The Staking & Fund Flow Mechanic

This is what makes it real and not just a toy:

Users deposit funds and choose a side (Bull or Bear)

Their deposit is locked into a smart contract escrow

Each round, a small % of the losing side's escrow flows to the winning side via Uniswap swap

Nobody loses everything in one round — conviction moves gradually (think Elo rating)

At the end of a defined period (e.g., 24 hours), final conviction scores determine total payout split

Example:

- \$500 staked on Bull side
- \$500 staked on Bear side
- After 10 rounds, Bear wins 7/10
- Bear conviction final: 68, Bull: 32
- Uniswap swaps redistribute: Bear stakers get ~68% of total pool
- KeeperHub executes this final settlement with full audit trail

🔧 How Each Partner Track is Deeply Satisfied

🦄 Uniswap — Not just bolted on

Every conviction threshold crossing triggers a real Uniswap swap

The staking pool itself is denominated in a Uniswap-supported pair (e.g., ETH/USDC)

Final settlement is a Uniswap swap

Intermediate round micro-settlements are Uniswap swaps

You use the Uniswap API for routing, not just raw contracts — which is exactly what they ask for

Include FEEDBACK.md documenting your full experience with the API

🌐 Gensyn AXL — The entire communication layer

Bull, Bear, and Judge agents run on three separate AXL nodes

Every argument, counter-argument, and verdict is a peer-to-peer AXL message

No central server, no message broker — fully satisfies their hard requirement

Agent discovery happens over AXL mesh (Bull and Bear find Judge automatically)

All messages are end-to-end encrypted by default — debate integrity is provable
You can demo this by showing three terminal windows, each an AXL node, messages flowing between them live

♥ KeeperHub — The execution reliability layer

Every swap triggered by conviction threshold goes through KeeperHub
If gas spikes mid-debate round, KeeperHub retries — debate doesn't break
MEV protection on settlement swaps (nobody can frontrun the final payout)
Full audit trail of every swap — when it was triggered, which agent won, what was executed
This audit trail is your legal-grade proof that the debate outcome was honored
Use KeeperHub MCP server for native agent integration
Submit your UX friction notes for the \$500 Builder Feedback Bounty — free extra prize

🖥️ What the Demo Looks Like (for your 4-min video)

0:00 - 0:20 Problem statement: prediction markets are static, no reasoning shown
0:20 - 1:00 Show three AXL nodes live — Bull, Bear, Judge terminals
1:00 - 2:00 Trigger a debate round live:

- Bull argument appears in terminal
- Bear counter appears
- Judge verdict published
- KeeperHub logs show swap queued
- Uniswap swap executes onchain

2:00 - 3:00 Show the smart contract escrow updating
Show conviction scores moving on a simple UI

3:00 - 3:30 Show final settlement — KeeperHub audit trail

3:30 - 4:00 "What this enables" — any two opposing agents,
any asset, fully autonomous debate-driven markets

📋 Submission Checklist

GitHub repo with clear README and setup instructions
FEEDBACK.md in repo root ← mandatory for Uniswap prize
3 AXL nodes demonstrated communicating across separate processes
KeeperHub write-up explaining how execution is used
All AI tool usage documented (attribution required per rules)
Version control showing incremental commits throughout hackathon

Demo video 2–4 mins, min 720p, no AI voiceover

Contract deployment addresses

Architecture diagram (strongly recommended by OG, good practice generally)

Why This Wins

Technicality — three integrated systems, novel agent coordination pattern

Originality — prediction markets exist, AI agents exist, but debating agents that move real liquidity does not

Practicality — anyone can stake on a token debate; the use case is immediately obvious

WOW Factor — watching two AIs argue about ETH in real time while money moves is inherently memorable

All three partners feel deeply used, not just mentioned
